

RESULTS SO FAR

– **Aim:** predict unexpected readmission or mortality after ICU discharge

– **Data** on 17k ICU patients (2010–2018) of VUmc Amsterdam

– Interpretable **feature extraction** from time series of signals

– **Gradient Boosting** classifier with cross-validated AUC of 0.82

– **Software** developed in close collaboration with VUmc, User studies: software tested with 20 intensivists

NEXT STEPS 2019/2020

– CE-marking and Academic publication

– **External validation** at 3 hospitals and **prospective validation** at VUmc

– **Implementation** and scaling

1

A huge amount of patient characteristics are measured continuously at the ICU

2

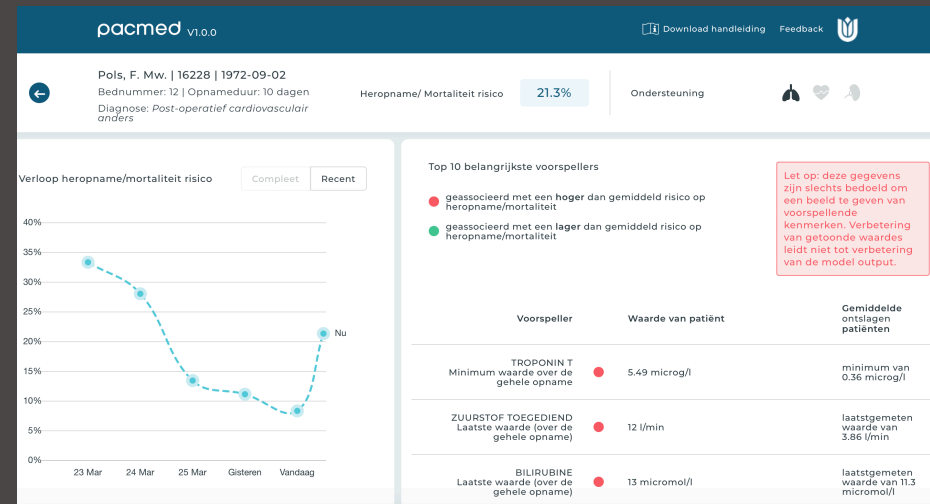

Deciding if a patient is eligible for discharge is complex
5–7% of discharges lead to readmission or mortality

The journey
from data to
decision
support

3

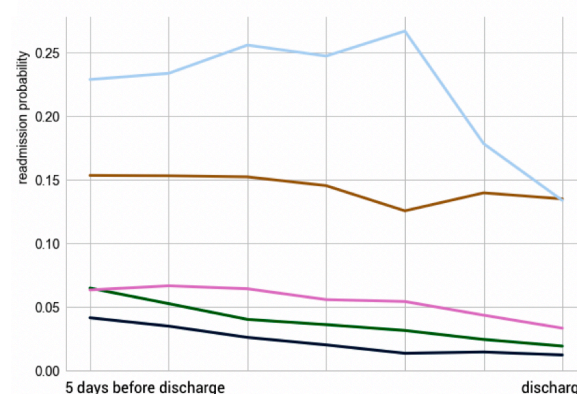

We translate all patient measurements into statistics that are predictive of unsuccessful discharge

6

The prediction and most important features are presented within a decision support tool

Avg. readmission prob. five days before discharge until moment of discharge
patient groups made based on rate of improvement

5

Patients that potentially could have been discharged earlier or later can be identified

4

SHAP is used to open the black box of a Gradient Boosting model that predicts outcome of discharge
